NOAA's National Oceanographic Office has compiled all the available information about the coral reef systems of the Caribbean into a downloadable file called A Reef Guide to the Caribbean. "No one could set foot in the sea without killing and eating a creature that would in another place have been a living temple of God.". That the evolution has been so slowed up here in this small area is a sad commentary on the lack of a good earth-mother in this area. Q: How much do coral reefs protect the coastline? A: Reefs protect land by acting as a natural barrier against destructive waves and by trapping sand on the coast during storm events. How the coral reef looks, how the coral looks, that's the dream of the islander. I believe the coral reefs are responsible for the biogeochemistry of the oceans. The accumulation of organic carbon and phosphorus on the reef is essential to its productive fisheries. This theory was pioneered by Roger Revelle, who died in 1990, before his research became accepted and widely appreciated. A petrified Eden A reef consists of a variety of organisms, including corals, sponges, tube worms, sea anemones, sea cucumbers, barnacles, and other organisms such as sea stars and sea urchins. The Eastern Tropical Pacific reef around the coasts of Mexico and the Central America is renowned as the world's richest coral reef ecosystem, and is a UNEP (United Nations Environmental Programme) World Heritage Site. Even with the worldwide trend of worsening living conditions, the United States of America does appear to be far more environmentally friendly than most other countries. This is not surprising, since the USA was the first country to set aside land as a National Park. Corals are closely linked to the ocean, and the inshore coral ecosystems are under threat from a number of causes. Thus, in the 1950s, scientists came to the conclusion that a "natural equilibrium" existed between the ocean and the land, and that reefs were, as yet, in a state of near stability. But that notion was challenged by studies of coral reefs published in the 1980s that showed them to be highly dynamic ecosystems. Despite the damage to some reefs, scientific research over the past decade or so has shown that most corals are quite resilient, and are able to survive and even thrive in the face of major disturbances. Coral reefs are living creatures and the reef supports many forms of life, such as sea urchins, anemones and algae, as well as fish, reptiles, birds and mammals 82157476af
